Subject: 10/054,536

Good morning:

1) Please perform a sequence and an interference search for SEQ ID NO: 2 in application SN 10/054,536. Please run the sequence also in amino acid sequence databases.

2) Please include a search for inventor's name: Nobutaka Wakamiya

Thanx.

S. DEVI, Ph.D.
AU 1645

AB It is intended to disclose an anti-HIV agent which contains as the active ingredient a mannose-binding protein (MBP) and efficaciously contributes to the treatment of patients infected with human immunodeficiency virus (HIV) and inhibits the progress of the disease. It is also intended to disclose a method of evaluating an anti-HIV activity exerted by the MBP which involves the step of culturing HIV-infected cells in the presence of the MBP.

AB Calcineurin and calcium/calmodulin-dependent protein kinase (CaMK) II have been suggested to be the signaling molts. in cardiac hypertrophy. It was not known, however, whether these mechanisms are involved in cardiac hypertrophy induced by pressure overload without the influences of blood-derived humoral factors, such as angiotensin II. To elucidate the roles of calcineurin and CaMK II in this situation, we examined the effects of calcineurin and CaMK II inhibitors on pressure overload-induced expression of c-fos, an immediate-early gene, and protein synthesis using heart perfusion model. The hearts isolated from Sprague-Dawley rats were perfused according to the Langendorff technique, and then subjected to the acute pressure overload by raising the perfusion pressure. The activation of calcineurin was evaluated by its complex formation with calmodulin and by its R-II phosphopeptide dephosphorylation. CaMK II activation was evaluated by its autophosphorylation. Expression of c-fos mRNA and rates of protein synthesis were measured by northern blot anal. and by ¹⁴C-phenylalanine incorporation, resp. Acute pressure overload

significantly increased calcineurin activity, CaMK II activity, c-fos expression and protein synthesis. Cyclosporin A and FK506, the calcineurin inhibitors, significantly inhibited the increases in both c-fos expression and protein synthesis. KN62, a CaMK II inhibitor, also significantly prevented the increase in protein synthesis, whereas it failed to affect the expression of c-fos. These results suggest that both calcineurin and CaMK II pathways are critical in the pressure overload-induced acceleration of protein synthesis, and that transcription of c-fos gene is regulated by calcineurin pathway but not by CaMK II pathway.

AB A total of 21 clones of acyclovir (ACV)-resistant (ACVr) herpes simplex virus type 1 (HSV-1) and 23 clones of penciclovir (PCV)-resistant (PCVr) HSV-1, emerging during serial passages in the presence of ACV or PCV, were isolated under conditions excluding contamination of resistant mutants in the starting virus culture, and their mutations in the thymidine kinase (TK) and DNA polymerase (DNA Pol) genes were analyzed comparatively. Mutations in the TK genes from ACVr mutants consisted of 50% single nucleotide substitutions and 50% frameshift mutations, while the corresponding figures for the PCVr mutants were 4 and 96%, resp. ($P < 0.001$). Eight of the 21 ACVr clones, but none of the 23 PCVr clones, had mutations in DNA Pol. Only nucleotide substitution(s) could be detected in the DNA Pol gene, as the gene is essential for virus replication. Therefore, the results for the DNA Pol mutants are concordant with those for the TK mutants in that a single nucleotide substitution was commonly observed in the ACVr, but not in the PCVr, mutants. These results clearly point to differential mutation patterns between ACVr and PCVr HSV-1 clones.

AB Collectins are a family of C-type lectins found in vertebrates. These proteins have four regions, a relatively short N-terminal region, a collagen-like region, an alpha-helical coiled coil, and a carbohydrate recognition domain. Collectins are involved in host defense through their ability to bind carbohydrate antigens on microorganisms. Type A scavenger receptors are classical-type scavenger receptors that also have collagen-like domains. We previously described a new scavenger receptor, collectin from placenta [collectin placenta 1 (CL-P1)]. CL-P1 is a type II membrane protein with all four regions. We found that CL-P1 can bind and phagocytize both bacteria and yeast. In addition to that, it reacts with oxidized low-d. lipoprotein (LDL) but not with acetylated LDL. These results suggest that CL-P1 might play important roles in host defenses and/or atherosclerosis formation. One rational strategy to study the role of CL-P1 in these pathol. conditions would be to perform a haplotype association study using human samples. As a first step for this strategy, we analyzed the haplotype structure of the CL-P1 gene. By sequencing the CL-P1 gene in ten Japanese volunteers, we identified five single-nucleotide polymorphisms (SNPs) with a minor allele frequency of at least 29%. To obtain SNPs in the 5'-upstream region of the gene, we screened a total of 20 SNPs described in the database and finally picked up one SNP for the present study. Thus, a total of six SNPs, one in the 5'-upstream region, two in intron 2, one in exon 5, and two in exon 6, were used to analyze the haplotype structure of the gene, with DNAs derived from 54 individuals (108 alleles). The anal. revealed that only two of six SNPs showed significant linkage disequil. ($r^2 > 0.5$) with each other. This haplotype information may be useful in disease-association studies in which a contribution of the CL-P1 gene has been suspected, especially in immunol. disturbance or atherosclerosis. Two SNPs in exon 6, both leading to amino acid substitutions, could be candidates for influencing disease susceptibility.

AB Collectins are members of the superfamily of vertebrate C-type lectins that contain a collagen-like region, and are involved in first-line host defense. We earlier cloned and characterized a new kind of collectin, collectin liver 1 (CL-L1). In this study, we isolated the mouse homolog of CL-L1 encoding 277 amino acid residues; its deduced protein sequence was 88% identical with human CL-L1. Mouse CL-L1 mRNA was expressed mainly in the liver and stomach, but was found also in muscles, testes, intestines, and embryos. In mouse embryos, the level of CL-L1 mRNA

gradually increased with embryonic age. In 16-day-old mouse embryos, CL-L1 mRNA was expressed in the liver, amnion, and visceral yolk sac. The mouse CL-L1 gene was found on chromosome 15 in a region syntenic with human chromosome 8q. CL-L1 was a highly conserved protein in mammals, birds, and fish.

LANGUAGE: English

AB In response to oxidative stress, the pathogenesis of a number of cardiovascular events and several genes are stimulated by extracellular signal-regulated kinases (ERK1/2). Biphasic (early, 10 min; and delayed, 120 min) ERK1/2 activation by H₂O₂, a reactive oxygen species, was observed in cultured neonatal rat cardiomyocytes. We investigated the hypothesis that the delayed activation of ERK1/2 depends on a factor secreted by oxidative stress (FSO). The delayed activation was inhibited by calphostin C, a protein kinase C inhibitor. Conditioned medium (CM) obtained from cells stimulated with H₂O₂ induced rapid and monophasic ERK1/2 activation, which was not inhibited by calphostin C. In contrast, calphostin C-pretreated CM did not activate ERK1/2. Macrophage migration inhibitory factor (MIF) was one of the candidate FSOs activating ERK1/2. The existence of MIF in CM, the recombinant MIF-stimulated ERK1/2 rapid activation, and anti-MIF neutralizing antibody-induced inhibition of the delayed activation implied that MIF could be the FSO. Pretreatment of cardiomyocytes with a mitogen-activated protein kinase/ERK kinase (MEK) inhibitor did not suppress the MIF secretion, although it prevented the ERK1/2 activation by H₂O₂. These results indicate that MIF is secreted from cardiomyocytes as a result of oxidative stress and activates ERK1/2 through a MEK1/2-dependent mechanism, although the secretion is not regulated by ERK1/2 but by protein kinase C.

AB Mannose binding lectin (MBL) binding initiates activation of the lectin complement pathway. Recent studies from our laboratory have demonstrated that MBL-dependent complement activation mediates cellular injury following oxidative stress in vivo and in vitro. A panel of novel inhibitory monoclonal antibodies (MAbs) against MBL (e.g., MAb 3F8, 2A9, and hMBL1.2) has been developed that inhibit MBL binding and lectin pathway activation. Here, we further characterized the interactions of these MAbs and their Fab fragments to MBL. Whole MAbs or their Fab fragments bound to MBL with relatively high affinity. Fab fragments of 3F8 were functionally effective in inhibiting MBL-dependent complement activation, however, steric hindrance of MAb 2A9 was essential for inhibition of MBL-dependent complement activation. We identified the hinge region, and residues EDCVLL within the carbohydrate recognition domain of MBL as the recognition sites for MAb 3F8 and 2A9, resp. The interaction of MAbs (e.g., 3F8 and 2A9) to MBL was dependent on the conformation of their recognition sites. These findings demonstrate that MBL binding can be inhibited by at least two sep. and independent mechanisms.

DOCUMENT TYPE: Journal

LANGUAGE: English

AB The mannose-binding lectin (MBL) gene was reported to play an important role in determining the clin. outcome of persistent hepatitis B virus (HBV) infection. We investigated serum MBL concns. and MBL gene mutations to determine whether they were related to the prognosis of patients with fulminant hepatic failure (FHF) caused by HBV infection. We investigated serum MBL concns. and MBL gene mutations in 43 HBV-infected Japanese patients with FHF and 260 HBsAg-neg. healthy controls. Serum MBL concns. were measured by an ELISA, and mutations in the MBL gene were analyzed by nested PCR and direct DNA sequencing. Only a mutation in codon 54 of the MBL gene was found. The frequency of this mutation in nonsurvivors (40%, 8/20) was higher than in survivors (13%, 3/23), and the difference was slightly significant ($p = 0.043$). The H allele frequency in survivors (70.5%, 31/44) was higher than in nonsurvivors (39.5%, 15/38) ($p = 0.0048$). Because of these factors the mean serum MBL concentration in survivors, 1.61 $\mu\text{g/mL}$ (range 0.3-3.86), was significantly higher than in nonsurvivors, 0.79 $\mu\text{g/mL}$ (range 0.04-1.51) ($p < 0.0001$). The likelihood ratio for nonsurvival was 0 for over 2.0 $\mu\text{g/mL}$, 0.67 for 1.0-2.0 $\mu\text{g/mL}$, and 2.24 for 0-1.0 $\mu\text{g/mL}$. The mutation in codon 54 of the MBL gene tended to be higher in nonsurvivors than in survivors. The H allele frequency (high producing allele in H/Y) in survivors was higher than that in nonsurvivors. High levels of serum MBL correlated with the survival of patients with FHF due to HBV infection. Serum MBL may be useful as a predictive factor for the survival of patients with FHF caused by HBV.

AB The invention provides the cDNA and protein sequence of human and mouse collectins (CL-L2) and splicing derivs. of CL-L2 cloned from EST(expression sequence tags). The CL-L2s contain Gly-Xaa-Yaa repeating motif in N-terminal of the sequence and CRD domain. The purified CL-L2 provided in this invention showed carbohydrate binding activity. The invention also provides the tissue distribution of CL-L2 genes. The CL-L2s can be used for drug screening for identification of agonists and antagonists against CL-L2.

AB Novel scavenger receptor SRCL-P1 from human and mouse having an SR structure and a collectin-like domain, cDNAs, recombinant expression, transgenic or knockout animal, antibodies and use in drug screening, are disclosed. Using a human placenta cDNA library, cDNA for a novel member belonging to the scavenger receptor family was cloned. Complementary DNA of this clone encodes a type II transmembranous glycoprotein containing a collagen-like domain, which are typical structural characteristics of scavenger receptor class A. This protein also contains a C-type lectin/carbohydrate recognition domain (C-type CRD) located at the C-terminus. We designated this as Scavenger Receptor with C-type Lectin (SRCL). When SRCL-P1 were expressed in CHO cells, they were localized in the plasma membrane forming clusters on the surface. Ligand-binding studies of CHO cells expressing SRCL-P1 demonstrated their specific binding capacity in Escherichia coli and Staphylococcus aureus as well as oxidized LDL and advanced glycation end products (AGE).

AB Mannose-binding lectin (MBL) is a key element of the innate immunity, with a structure similar to complement C1q. Serum MBL levels are greatly affected by the polymorphisms of the MBL gene. In particular, codon 54 mutation of the MBL gene results in a significant reduction of serum MBL. To determine whether polymorphism of the MBL gene is associated with occurrence of systemic lupus erythematosus (SLE), rheumatoid arthritis and Sjogren's syndrome in the Japanese population, we analyzed the MBL gene polymorphisms of these patients and controls, by polymerase chain reaction-restriction fragment length polymorphism methods. We found that patients studied had a significantly higher frequency of having homozygous codon 54 mutation compared to controls. In particular, patients with SLE or Sjogren's syndrome showed higher probabilities of being homozygous for this mutation. Among subjects with the same genotype, SLE patients tended to have higher serum MBL concentration than controls. Anal. of the promoter region suggested that SLE patients heterozygous for the codon 54 mutation have a higher probability of having a low producing haplotype for the gene without the codon 54 mutation. We conclude that persons homozygous for

codon 54 mutation of the MBL gene may be prone to occurrence of autoimmune disorders including SLE, in the Japanese. MBL may have protective effects on occurrence and progression of SLE.

AB Mannan-binding lectin (MBL) constitutes an important part of the innate immune defense by effecting the deposition of complement on microbial surfaces. MBL deficiency is among the most common primary immunodeficiencies and is associated with recurrent infections and symptoms of poor immune complex clearance. Plasma-derived MBL has been used in reconstitution therapy but concerns over viral contamination and production capacity point to recombinant MBL (rMBL) as a future source of this protein for clin. use. Natural human MBL is an oligomer of up to 18 identical polypeptide chains. The synthesis of rMBL has been accomplished in several mammalian cell lines, however, the recombinant protein differed structurally from natural MBL. In this, study the authors compare rMBL produced in myeloma cells, Chinese hamster ovary (CHO) cells, human hepatocytes, and human embryonic kidney (HEK) cells. The authors report that rMBL structurally and functionally similar to natural MBL can be obtained through synthesis in the human embryonic kidney cells followed by selective carbohydrate affinity chromatog.

AB With the exception of humans and chickens, the Hanganutziu-Deicher antigen is widely distributed in the animal kingdom. This suggests that the HD antigen could cause a strong humoral response in swine-to-human transplantation after the hyperacute rejection is avoided. The present study was designed to evaluate the possibility that the HD antigen on swine endothelial cells could be downregulated to the overexpression of various glycosyltransferases. Results indicate that human β -1,4-N-acetylglucosaminyltransferase III has the potential to reduce HD antigen levels on swine endothelial cells.

AB Persistent infection with hepatitis C virus (HCV) leads to liver cirrhosis (LC) and often to liver cancer. Little is known about host factors that determine the variable natural history. Mannose-binding lectin (MBL) is an important constituent of the innate immune system. In white patients there is an association between codon 52 mutation of the MBL gene and persistent hepatitis B virus (HBV) infection. To determine whether MBL gene polymorphisms affect the course of HCV infection, the authors investigated the association between MBL gene polymorphisms and HCV infection in Japanese subjects. Fifty-two HCV-infected Japanese patients (8 with chronic inactive hepatitis (CIH), 31 with chronic active hepatitis (CAH), 13 with LC) and 50 normal controls were studied. MBL gene mutations were determined by polymerase chain reaction and restriction fragment length polymorphism analyses. Codon 52 and codon 57 mutations were absent in all subjects. Homozygous mutation in codon 54 was present in one (0.9%) patient. Heterozygous codon 54 mutation was present in 17 (32%) of the 52 patients and in 21 (41%) of the controls. No significant difference in the frequency of codon 54 mutation was observed between patient and control groups. However, although no significant relation was observed between MBL polymorphisms and the levels of HCV RNA, all patients with heterozygous or homozygous codon 54 mutations had CAH or LC. In contrast, 8 of the 34 patients without codon 54 mutation remained at CIH. MBL may be one of the factors that influence the course of HCV infection.

AB Fab fragments of a wild type or mutants of an anti-(4-hydroxy-3-nitrophenyl)acetyl mAb, B2, were expressed on the surface of a filamentous phage in order to examine the role of conserved amino acid residues at positions 32, 50, and 60 in complementarity determining regions. These had been predicted previously as specificity-determining residues. Phages expressing mutant Fabs with replacement of a single amino acid at these positions in complementarity determining regions of the heavy-chain V region showed a large to complete loss of ability to bind haptens. In addition, substitution of Tyr60 hindered formation of Fab, suggesting that this amino acid residue is critical for the interaction between V domains in heavy and light chains. Thus, the amino acid residues conserved in somatic mutation of complementarity determining regions are important in determining Ab-specificity as well as in inter-V domain interactions.

AB Described is a method of producing human mannan-binding protein (rhMBP) by expression of the encoding cDNA in a host cell followed by chromatog. purification. The rhMBP purified by gel filtration exhibits a peak absorption at 280 nm and mol. weight 300- or 1,150 kDa. Expression of rhMBP in the transgenic dihydrofolate reductase-deficient CHO cells from plasmid pNOW1-hMBP was demonstrated. The rhMBP is able to block the influenza virus-mediated erythrocyte agglutination.

AB Mannan-binding lectin (MBL) is a C-type serum lectin that is believed to play an important role in innate immunity. It is one of the collectin family, which is characterized by having a collagen-like sequence and a carbohydrate recognition domain. MBL can bind to sugar determinants of several micro-organisms, neutralize them and inhibit infection by complement activation through the lectin pathway and opsonization by collectin receptors. Bovine conglutinin and mouse MBL inhibit the infective and hemagglutinating activities of influenza A viruses. To identify the direct antiviral activity of human MBL against influenza A viruses that does not depend on complement activation or opsonization, the authors isolated native MBL from human serum and produced a recombinant

MBL in Chinese hamster ovary (CHO) cells using a pNOW/CMV-A expression vector system. Native and recombinant human MBL exhibited neutralization activity against A/Ibaraki/1/90 (H3N2), with the plaque focus reduction assay at the viral attachment phase. Their activities were inhibited by EDTA, mannose and anti-human MBL antibody. Furthermore, at the viral expansion phase both MBL in culture medium prevented viral spreading from primary infected cells to neighbor cells. A virus recovery study using EDTA indicated that interaction between MBL and virus was reversible and non-damaging to the virus. Lectin blot and immunohistochem. assays showed that these antiviral activities involved binding between MBL and two viral envelope proteins, hemagglutinin and neuraminidase. These findings suggest that human MBL can play an important role in innate immunity by direct viral neutralization and inhibition of viral spread, as well as an indirect role through opsonization and complement activation.

LANGUAGE: English

AB Collectins are a C-lectin family with collagen-like sequences and carbohydrate recognition domains. These proteins can bind to carbohydrate antigens of microorganisms and inhibit their infection by direct neutralization and agglutination, the activation of complement through the lectin pathway, and opsonization by collectin receptors. Here we report the cloning of a cDNA encoding human collectin from liver (CL-L1 (collectin liver 1)) that has typical collectin structural characteristics, consisting of an N-terminal cysteine-rich domain, a collagen-like domain, a neck domain, and a carbohydrate recognition domain. The cDNA has an insert of 831 base pairs coding for a protein of 277 amino acid residues. The deduced amino acid sequence shows that this collectin has a unique repeat of four lysine residues in its C-terminal area. Northern blot, Western blot, and RT-PCR analyses showed that CL-L1 is present mainly in liver as a cytosolic protein and at low levels in placenta. More sensitive analyses by RT-PCR showed that most tissues (except skeletal muscle) have CL-L1 mRNA. Zoo-blot anal. indicated that CL-L1 is limited to mammals and birds. A chromosomal localization study indicated that the CL-L1 gene localizes to chromosome 8q23-q24.1, different from chromosome 10 of other human collectin genes. Expression studies of fusion proteins lacking the collagen and N-terminal domains produced in *Escherichia coli* affirmed that CL-L1 binds mannose weakly. CL-L1 and recombinant CL-L1 fusion proteins do not bind to mannan columns. Anal. of the phylogenetic tree of CL-L1 and other collectins indicated that CL-L1 belongs to a fourth subfamily of collectins following the mannan-binding protein, surfactant protein A, and surfactant protein D subfamilies including bovine conglutinin and collectin-43 (CL-43). These findings indicate that CL-L1 may be involved in different biol. functions.

 AB We have developed a high-expression system of recombinant human mannan-binding lectin (MBL) with CHO cells. Geneticin-resistant transformants harboring human MBL cDNA in the expression vector pNOW/CMV-A were screened by immunoblot anal. for secretion of recombinant MBL. Cloning and selection by both geneticin and methotrexate resulted in the production of recombinant MBL to a final concentration of 128.8 µg/mL in media after four days of culture. SDS-PAGE and gel-filtration analyses showed that recombinant MBL is characterized by two lower-order oligomeric structures (apparent mol. wts.: 1150 kDa and 300 kDa) compared to native MBL (apparent mol. weight: 1300 kDa). The recombinant human MBL has both sugar-binding and complement activation activity and, like native MBL, can inhibit hemagglutination of influenza A virus. Lectin blots with recombinant MBL indicate that it can bind such microorganisms as HIV and influenza virus suggesting that it might inhibit their infection of hosts. This high-level expression of human MBL with the full range of biol. activity will be useful for studies on the immunol. role of MBL in humans.

 AB Mannan-binding protein (MBP) is a calcium-dependent mammalian serum lectin important in first-line host defense. MBP belongs to the collectin family, which is characterized by an NH2-terminal cysteine-rich domain, a collagen-like domain, a neck domain, and a carbohydrate recognition domain (CRD). Recombinant human MBP, consisting of the short collagen region (2 repeats of Gly-Xaa-Yaa amino acid sequences), the neck domain, and the CRD, was expressed in E. coli. The truncated MBP was capable of forming

trimers by association of the neck domain and could bind sugar with a specificity similar to that of the native form. Results of hemagglutination inhibition (HI) assay of influenza A virus showed that the truncated MBP inhibited hemagglutination less strongly, although the native MBP induced the HI phenomenon. These results suggest that an oligomeric structure is an advantage for MBP to have full biol. activity against influenza A virus.

AB Mannan-binding protein (MBP) is a member of the collectin family of protein. There are two types of MBP, MBP-A and MBP-C, which were found in rodent (rats and mice), rhesus monkey, and cynomolgus monkey, while chimpanzee and human have only one MBP. It was considered that the loss of one MBP gene occurred during hominoid evolution. In this article two rabbit MBP, a liver and serum MBP, were characterized biol. and genetically. Analyses by SDS-PAGE under reduced condition and their amino acid sequences of both MBPs showed that they have a same mol. weight of 32 kDa and their amino acid sequences were identical. A serum MBP has a higher ability to activate complement than does a liver MBP; however, a liver MBP inhibits hemagglutination by influenza virus as strongly as a serum MBP does. The cDNA clones encoding the rabbit MBP were isolated from a rabbit cDNA liver library using whole cDNA of mouse MBP-C as a probe. The cDNA carried an insert of 744 bp coding for a protein of 247 acid residues with a signal peptide of 22 residues. The deduced amino acid sequence of the cDNA was identical to that of amino acid sequences of the 32-kDa proteins determined here. Northern blot anal. showed that mRNA transcripts of about 0.9 and 3.0 kb were expressed only in the liver. The anal. of the phylogenetic tree of rabbit and bovine MBPs and other collectins indicates that the loss of MBP gene occurred not only during hominoid evolution but also at some points after the separation of birds and mammals.

AB The successful expression of recombinant bovine conglutinin in CHO cells is described as well as its phys. and biol. characteristics. Geneticin-resistant transformants harboring bovine conglutinin cDNA in the expression vector pNOW/CMV-A were screened by Western blot anal. for secretion into media of recombinant conglutinin. A 4-day amplification of the transgene with increasing concns. of methotrexate resulted in a dose-dependent increase in the production of recombinant conglutinin to a final concentration of 18.6 µg/mL of media. Recombinant conglutinin purified from this media by affinity column chromatog. on mannan-agarose had a migration pattern similar to that of native conglutinin on PAGE under reducing, nonreducing, and native conditions. Recombinant conglutinin exhibited sugar binding, conglutination, hemagglutination inhibition, and neutralization of influenza A virus, activities engaged in by the native conglutinin. This is the 1st report describing a high level of expression of a serum cruciform collectin with the full range of biol. activity.

AB Monocytes/macrophages have been known to play an important role in the initiation and propagation of human immunodeficiency virus 1 (HIV-1) infection. To analyze the function of these cells during the clin. asymptomatic period of infection, the authors examined the effect of murine peritoneal macrophages and human peripheral blood macrophages on 2 cell lines latently infected with HIV-1, a promonocytic cell line, U1, and a T-cell line, ACH-2. Monokines of the murine peritoneal macrophages induced viral expression in U1, but not in ACH-2 cells. Expts. employing transient transfection of U937 and CEM cells with HIV long terminal repeat (LTR)-chloramphenicol acetyl transferase (CAT) plasmids indicated that the effect of these monokines was due to specific activation of the HIV LTR. In contrast, supernatants of human macrophages induced viral expression in both ACH-2 and U1 cells. Thus, several monokines are active in regulating the transition from the clin. asymptomatic period of HIV infection to progression to AIDS.

AB Surfactant protein D (SP-D) is a lung-specific protein that is synthesized and secreted by lung epithelial cells and is believed to play an important role in lung host defense. This protein belongs to the C-type lectin family, which is characterized by an N-terminal cysteine-rich domain, a collagen-like domain, a neck domain and a carbohydrate recognition domain (CRD). To elucidate the biol. actions of this animal lectin against such pathogens as micro-organisms, the biol. activities of a recombinant partial SP-D lacking a collagen-like domain were examined. A recombinant human SP-D, consisting of a short collagen region (two repeats of Gly-Xaa-Yaa amino acid sequences), the neck domain and the CRD, was expressed in Escherichia coli. The recombinant SP-D was purified on a nickel column and then on a maltose-agarose column. This protein can form a trimeric structure owing to the neck domain and exhibits sugar-binding activity and specificity similar to those of native human SP-D. The recombinant SP-D caused dose-dependent and calcium-dependent agglutination of E. coli Y1088. The agglutination titer (the concentration required to achieve a 50% decrease in light transmission by agglutination) of recombinant SP-D was approx. 6-fold that of native SP-D. As for conglutination, the recombinant trimeric conglutinin required 8-16-fold higher concns. than the native counterpart. In hemagglutination inhibition (HI) of influenza A virus, although native and recombinant conglutinin showed similar levels of HI activity, the recombinant SP-D was unable to inhibit hemagglutination, even at a concentration approx. 120-fold that of the native SP-D. The lectin precipitation and lectin blot assays showed that the truncated SP-D could bind to influenza A virus as well as native SP-D did. These results indicate that the agglutination activity of trimeric collectins can be largely retained, and furthermore that the oligomeric structure with several hands at opposite sites can enhance agglutination activity. The difference in HI activity against influenza A virus between native and recombinant SP-D suggests that SP-D uses a different mechanism from that of conglutinin to inhibit viral hemagglutination.

AB Disclosed is a recombinant conglutinin which contains a collagen region consisting of six amino acids comprised of 2 oligopeptides Gly-Xaa-Xaa, the neck region of natural conglutinin, and the sugar chain recognition region of natural conglutinin. The recombinant conglutinin exhibits

antiviral activity (virus neutralizing activity) that has medical applications. Also disclosed is a process for detecting anti-influenza A virus activity of a mannose-binding protein (MBP) or a human mannose-binding protein (hMBP), which process involves treating influenza A virus-infected cells with the MBP or hMBP and measuring the level of the suppression of the budding of the virus in the virus-infected cells. An MBP and an hMBP having an anti-influenza A virus activity are disclosed.

AB Feline immunodeficiency virus (FIV) infection in cats has been reported to be a useful animal model for human AIDS studies, especially in the early stages of infection. The authors examined the temporal changes in provirus detection in peripheral blood mononuclear cells (PBMC) and the distribution of FIV-DNA and RNA in feline tissues by the polymerase chain reaction at 10, 35, 70 days after i.v. inoculation of FIV. Viral DNA in the PBMC was detected three to four weeks after infection and its fluctuation was demonstrated for the first time. Ten days after infection, before seroconversion, proviruses were detected only in the mesenteric lymph nodes and intestines. At 35 and 70 days after infection, after seroconversion, proviruses were detected in most lymphoid organs and the salivary glands, but the expression of FIV-RNA was limited to the thymus at 70 days after infection. These results show that FIV-RNA is transcribed from proviral DNA exclusively in the thymus at this stage. The authors suggest that the quant. changes in detectable proviruses in the PBMC depend on the relation between the decrease in infected cells caused by cytolytic T lymphocytes and/or apoptosis and their increase caused by the release of a new supply of lymphocytes from the thymus.

AB To identify the bovine mannan-binding protein (MBP), a search for the cDNA homolog of human MBP was carried out. cDNA clones encoding bovine MBP were isolated from a bovine liver cDNA library using a cDNA fragment encoding a short collagen region, neck domain and carbohydrate recognition

domain of human MBP. The cDNA carried an insert of 747 bp encoding a protein of 249 amino acid (aa) residues with a signal peptide of 19 aa. The mannan-binding protein fraction of bovine serum that eluted with 100 mM mannose from a mannan-Sepharose column was analyzed under reducing conditions by SDS-PAGE. The major band of 33 kDa obtained reacted with anti-human MBP rabbit serum. The partial aa sequence of the purified 33-kDa protein was identical to the aa sequence deduced from the obtained cDNA. Results of the passive hemolysis experiment using sheep erythrocytes coated with yeast mannan suggest that this MBP has the ability to activate complement. Northern blot anal. showed a 1.8-kb mRNA that was expressed only in the liver. Based on results of genomic anal., this bovine MBP is likely to be a homolog of human MBP and to also have homol. to rat and mouse MBP-C which are localized in liver cells rather than to rat and mouse MBP-A found in serum. Alignments of bovine collectins show that bovine MBP cannot be included among the other bovine collectins, such as bovine SP-D, conglutinin and CL-43. Finally, these genomic and biol. analyses indicate that the cDNA obtained here encoded a bovine serum MBP.

AB Conglutinin is a bovine serum protein which was first described as a vertebrate lectin. This protein belongs to the family of C-type lectins. These lectins are composed of four characteristic domains: (1) an N-terminal cysteine-rich domain, (2) a collagen-like domain, (3) a neck domain and (4) a carbohydrate recognition domain (CRD). Recently lectins have been shown to function as Ig-independent defense mols. due to a complement-mediated mechanism or opsonization. Our previous study showed that bovine conglutinin can inhibit hemagglutination by influenza A viruses and act by directly neutralizing them due to its lectin properties. In order to elucidate the biol. role of the collagen-like domain, a recombinant partial conglutinin lacking this collagen-like domain was produced in an Escherichia coli system and its biol. activities were examined. A 497 bp sequence, consisting of a short collagen region (two repeats of G-X-Y amino acid sequences), the neck domain, and the CRD of conglutinin cDNA, was amplified by the reverse-transcriptase PCR technique. The cDNA was transferred to a bacterial expression vector system (pRSET-A) and stable transfectants with a high level of conglutinin production were obtained. SDS/PAGE and Western blotting analyses showed a recombinant fusion protein of 27 kDa. Results of a crosslinking study and gel-filtration assay indicated that the recombinant conglutinin can form a trimeric structure and that it has sugar binding activity and specificity similar to that of native conglutinin. The recombinant conglutinin was also found to inhibit hemagglutination caused by influenza A virus as well as to possess less conglutination activity. These results suggest that in order for conglutinin to inhibit hemagglutination caused by the influenza virus, as well as to have sugar binding activity or to form trimers, it does not require the N-terminal and collagenous domains; however, they are essential for full conglutination activity.

DOCUMENT TYPE: Journal

LANGUAGE: English

AB Levels and catalytic activities of cytochrome P 450 enzymes involved in the oxidation of drugs and carcinogens were determined in human adult lungs and fetal livers and compared with those in microsomes from adult livers. P 450 enzymes immunoreactive with anti-human P 4501A1 and anti-human P 4503A antibodies were detected in fetal liver microsomes by immunoblotting anal., and P 450s related to P 4501A1, 2A6, 2C9, 2E1, and 3A4 were determined in adult lung microsomes; all of these P 450 enzymes were detected in much higher amts. in adult liver microsomes except that P 4501A2 was only the 1A subfamily of P 450 found in adult livers. Drug oxidation activities with the substrates ethoxyresorufin, coumarin, 7-ethoxycoumarin, bufuralol, and testosterone were determined in these microsomes, and the authors found that none of the activities were higher in microsomes of adult lungs and fetal livers than in adult livers. Activation of procarcinogens to reactive metabolites that induce umu gene expression in Salmonella typhimurium TA1535/pSK1002 or NM2009 was also examined and it was found that activities with (+)- and (-)-enantiomers of 7,8-dihydroxy-7,8-dihydrobenzo[a]pyrene were higher in fetal liver microsomes than adult lung or liver microsomes. The adult liver and lung activities for these two procarcinogens were similar on the basis of microsomal protein contents despite the fact that P 450 contents are higher in liver than lung microsomes. α -Naphthoflavone, a known inhibitor of P 4501A-related activities, did not affect these procarcinogen activation in fetal liver microsomes. Fetal liver microsomes catalyzed activation of aflatoxin B1 and sterigmatocystin, two procarcinogens known to be activated by P 4503A4/7 in humans, although activation of carcinogenic arylamines that are good substrates for P 4501A2 was much lower in microsomes of fetal livers and adult lungs than in adult livers. These results suggest that in human fetal livers, at least two P 450 enzymes, a form of P 450 that is immunoreactive to P 4501A1 and P 4503A7, are actually expressed and these enzymes are suggested as being involved in the activation of the (+)- and (-)-enantiomers of 7,8-dihydroxy-7,8-dihydrobenzo[a]pyrene and the carcinogenic mycotoxins, resp. The exact nature of the former enzyme in fetal livers is unknown. In adult human lungs, several P 450 enzymes are expressed, although the precise roles of these enzymes in the oxidation of xenobiotics were not determined due to the low level of expression of these P 450s.

AB The authors have measured glycosyltransferase activities of SupT1 cells a T-lymphoid cell line shown to react with autoantibodies in the sera of many HIV patients. Since considerable α -N-acetylgalactosaminyl-transferase and β 1,3-galactosyl-transferase activities were found in SupT1 cells, at least the O-glycan core 1 structure can probably be synthesized. FACS anal. using an anti-T monoclonal antibody showed expression of the T antigen (Gal β 1-3 GalNAc). Glycoproteins with the T antigen were isolated by immunopptn. with the anti-T antibody from a SupT1 cell lysate labeled metabolically with 3H-glucosamine and then analyzed by SDS-PAGE. It was revealed that the precipitate contained a glycoprotein with a mol. weight corresponding to that of leukosialin. O-glycans were prepared from the immunoppt. by alkaline-borohydrate treatment and then fractionated on Bio-Gel P-2, GalNAcOH and Gal-GalNAcOH being identified inter alia. These results suggest that an anti-T antibody may be included in the auto-antibodies found in HIV-1 infected individuals.

AB A 912 bp bovine cDNA fragment encoding bovine conglutinin was amplified by the RT-PCR technique. Some cDNA clones encoding the bovine conglutinin were isolated from a bovine liver cDNA library using the specific probe obtained from the PCR product. These cDNAs carry an insert of 1113 bp coding for a protein of 371 amino acid residues with a signal peptide of 20 residues. The deduced amino acid sequence of cDNA agrees with that determined by conventional amino acid sequence anal. Two polyadenylation signal sequences were detected in the DNA sequence downstream of the 3' end of the gene. Southern blot anal. of total bovine genomic DNA indicated that there is only one copy of the gene encoding bovine conglutinin. Northern blot anal. of bovine tissues showed that conglutinin mRNA of about 1.5 kb is expressed in the liver and also slightly in the lung.

AB The antitumor activity of 7 sphingolipids (2 ceramides and 5

glycosphingolipids) against the syngeneic murine ascitic tumors MH134 and MM102 in C3H mice was examined. Five of these compds. showed anti-tumor activity against the tumors, ceramide type-IV (Cer-IV) having the highest activity without cytotoxic or cytostatic activity. These results indicate that the fatty acid in ceramide and sugar chains binding to it affect the antitumor activity in vivo. The antitumor activity of Cer-IV depended on the time of treatment. Mice treated with Cer-IV one day after tumor implantation showed the highest rate of survival. The cured mice were resistant to rechallenge with the same tumor (MH134 → MH134, MM102 → MM102) but not with a heterologous tumor (MH134 → X5563, MM102 → X5563), indicating that the effect of Cer-IV may be due to in vivo induction of specific immunity. Studies with various antibodies demonstrated that the anti-tumor effect of Cer-IV was inhibited by all the antibodies tested (L3T4, Lyt-2, and Thy-1,2 T cells, macrophages, and TNF α) in the induction phase (before Cer-IV administration) and by the antibodies of L3T4 and TNF α in the effector phase (after Cer-IV administration). Therefore, the anti-tumor effect of Cer-IV in this system depended on the host immune response rather than on its direct cytotoxic and/or cytostatic action.

LANGUAGE: English

AB As the majority of human immunodeficiency virus (HIV) carriers are in asymptomatic stage for a long period of time, it is important to investigate the factors or surrogate markers for conversion from asymptomatic to symptomatic stage. This study is designed to evaluate the relationship among virus isolation rate, anti-p17 antibody status, and progression to AIDS. The authors studied anti-p17 antibody status along with virus isolation in asymptomatic carriers and AIDS cases. Progression to AIDS was markedly associated with high rate of virus isolation and loss of anti-p17 antibody. In order to know the meaning of loss of anti-p17 antibody during the clin. course, anti-p17 antibody pos. and anti-p17 antibody neg. cases were followed up prospectively for the development of AIDS. None of the anti-p17 antibody pos. cases developed AIDS while 6 out of 16 anti-p17 neg. cases developed AIDS during observation period. Progression to AIDS was associated with loss of anti-p17 antibody. Identification of cases losing anti-p17 antibody in peripheral blood during asymptomatic period may help high-risk group who are in need of chemoprophylaxis. Moreover, study of anti-p17 antibody may be helpful in designing vaccine in future if it works as a neutralizing antibody to HIV in vivo.

AB Normal horse and guinea pig sera contain α 2-macroglobulin which inhibits the infectivity and hemagglutinating activity of influenza A viruses of the H2 and H3 subtypes. On the other hand, normal bovine serum contains a component termed β inhibitor that inhibits the infectivity and hemagglutinating activity of influenza A viruses of the H1 and H3 subtypes. To investigate the nature of the β inhibitor of influenza A virus, the conglutinin was purified and its characteristics examined. First, a high correlation was found between the hemagglutination inhibition (HI) titer and conglutinin titer in several bovine sera. The HI of bovine serum was mainly dependent on conglutinin because the HI activity was abrogated by N-acetylglucosamine but not by D-mannose. The conglutinin, purified from bovine serum, had neutralizing-activity as well as HI activity on influenza A viruses of the H1 and H3 subtypes. The HI activity of conglutinin was heat stable (56°, 30 min), Ca²⁺-dependent, and resistant to both neuraminidase and periodate treatments. The HI activity of purified conglutinin was blocked by N-acetylglucosamine but not by D-mannose. The conglutinin was bound to hemagglutinin which had high mannose and complex sugar chains and its binding was inhibited by N-acetylglucosamine and dependent on divalent cations. Thus, the β -like inhibitor activity of bovine serum is mainly dependent on conglutinin which inhibits hemagglutination and neutralizes the virus infectivity by its binding to a carbohydrate site on the HA.

AB Two chicken monoclonal antibodies (MAbs), HU/Ch2-7 and HU/Ch6-1, against heterophil Hanganutziu-Deicher (HD) antigens with N-glycolylneuraminic acid (NeuGc) at a terminal carbohydrate were established by cell fusions using chicken B cell lines lacking thymidine kinase and spleen cells from chickens immunized with II3NeuGc α -LacCer (HD3). The reactivities of these MAbs against several gangliosides including NeuGc-containing glycosphingolipids were examined by a TLC/immunostaining method. MAb HU/Ch2-7 (IgG) reacted strongly with HD3 and IV3NeuGc α -nLc4Cer (HD5) and weakly with VI3NeuGc α -nLc6Cer (HD7) and 4-O-acetyl-HD3. HU/Ch6-1 (IgG) reacted with HD3 and HD5, but did not react with the other HD antigens. The reactivities of these MAbs against HC antigen were greatly reduced by pre-treatment of the antigen with neuraminidase. These MAbs did not react with N-acetylneuraminic acid-containing gangliosides (GM1 and GM3). These results indicate that these two chicken MAbs are directed toward the antigenic epitope containing the NeuGc.

 AB Hanganutziu-Deicher (HD) antigen is a heterophile antigen that is widely distributed in many animals other than humans and chickens and is highly immunogenic in humans and chickens. In the present study, expression of HD-antigenic glycoproteins was demonstrated in activated T lymphocytes by SDS-PAGE and immunoblotting. Treatment with IL-2 plus PMA induced a 29kD glycoprotein antigen detected under reducing conditions. It contained sialic acid in the epitope of the HD antigen because the expression was neuraminidase-sensitive. Treatment with PMA plus A 23187 or phytohemagglutinin (PHA) treatment and then PHA plus IL-2 treatment also induced 2 proteins of mol. weight 50kD and 70kD. These were not detected in all individuals examined. Thus, HD antigen is an activated T cell antigen and expressed as an isoantigen as it is expressed in cancerous tissues from some patients.

 AB To visualize the antigen mols. of 9 species, immunostaining was used with avian anti-N-glycolylneuraminyl-lactosyl ceramide antibody which recognizes the terminal N-glycosylneuraminic acid moiety of glycoconjugates as an epitope of Hanganutziu-Deicher (HD) antigen. Several HD antigen-active glycoproteins were detected in the sera of fetal calf, calf, horse, goat, monkey, rabbit, guinea pig, rat and mouse, with the exception of human serum. The HD antigenic proteins showed heterogeneity in their MWs and were not identical with any major band visualized with silver-staining, indicating that they are major components of serum proteins in each animal. Neuraminidase treatment destroyed the antigenicity of all proteins.

AB Macrophage colony-stimulating factor (CSF-1) is a growth factor required for growth and differentiation of mononuclear phagocytes. The effects of CSF-1 are mediated through binding to specific, high-affinity surface receptors encoded by the c-fms gene. CSF-1 and c-fms gene expression was investigated in fresh human acute myeloblastic leukemic cells by Northern blot hybridization using cDNA probes. The 4.0-kb CSF-1 transcripts were detected in 10 of 17 cases of acute myeloblastic leukemia (AML), while c-fms transcripts were detected in 7 of 15. Coexpression of CSF-1 and c-fms was observed in 5 cases, and in 5 other cases neither gene was expressed. In situ hybridization demonstrated that transcripts for CSF-1 were present in 70-90% of cells in each of 3 cases studied while c-fms mRNA was detected in 40-70% of cells. The constitutive expression of CSF-1 transcripts was associated with production of CSF-1 protein, although detectable amts. of CSF-1 were not secreted unless the cells were exposed to phorbol ester. Thus, leukemic myeloblasts from a subset of patients with AML express transcripts for both the CSF-1 and CSF-1 receptor genes, often in the same leukemic cells in vitro.

AB Alkaline phosphatase detection of biotinylated gene v-fms and macrophage-specific colony-stimulating factor (CSF-1) cDNA probes in situ detected gene c-fms and CSF-1 transcripts in HL-60 cells induced along the monocytic lineage but not in uninduced cells. The specific detection of these transcripts is further supported by the absence of histochem. staining in RNase-treated cells and when using pBR322 plasmid without insert as the biotinylated probe. Finally, the results indicate that most of the induced HL-60 cells have detectable levels of both c-fms and CSF-1 RNA. This approach should be useful for studying expression of these genes in populations of leukemic blasts and normal hematopoietic cells.

 AB Monoclonal antibodies directed against major antigens induced by cowpox virus (CPV) were produced. The specificities of these antibodies were established by immunopptn., immunoblotting and several serol. analyses, and from the cross-reactivities of these antibodies with cells infected with various other poxviruses, ectromelia virus (EV), vaccinia virus, and Shope fibroma virus. The antibodies defined included ones reacting with each of the known major antigens of poxviruses, i.e. the common antigen of all poxviruses (probably NP antigen), the Orthopoxvirus-specific antigen (probably LS antigen), the hemagglutinin, the cell surface antigen, the common A-type inclusions in CPV and EV, and the antigen involved in neutralization.

 AB Several monoclonal antibodies recognizing distinct antigenic determinants in A-type inclusion bodies (ATIB) induced by cowpox virus (CPV) were obtained to examine the cross-reactivity among various strains of poxviridae, comprising CPV, ectromelia virus (EV), vaccinia virus (VV), and Shope fibroma virus (SFV). The monoclonal antibodies were classified into at least 3 groups on the basis of the results of an immunofluorescence test and immunoblotting; i.e., strain-specific, CPV and EV-specific and orthopoxvirus (CPV, EV and VV)-specific antibodies. Differences were found between the antigenic determinants of ATIB of LB strains (LB red and LB white) and other strains (Amsterdam, 53, 58 and 60) of CPV and also between those of ATIB of CPV and EV. Interestingly, VV also produces the antigen analogous to that associated with ATIB in CPV- and EV-infected cells despite the absence of morphol. defined ATIB.

AB The antigen in A type inclusion bodies (ATIB) induced by cowpox virus
(CPV) was examined by immunofluorescent staining with monoclonal antibodies
and polypeptide anal. In the immunofluorescence test, these monoclonal
antibodies reacted only with cytoplasmic inclusion bodies in cells
infected with CPV. The fluorescence became detectable in the cells 6-9 h
after infection with CPV. No fluorescence was detectable in cells
infected with CPV in the presence of Ara C or in cells infected with other
poxviruses, such as vaccinia virus (VV) or Shope fibroma virus (SFV). On
Western blotting and immunopptn. followed by SDS-PAGE, only 1 component
with a mol. weight of about 160,000 (160 K) was detected in CPV-infected
cells. This 160 K polypeptide was first detectable 12 h after infection
of cells with CPV, and was not detectable in infected cells in the
presence of Ara C. The 160 K polypeptide was not detected in cells
infected with VV or SFV, or in virions purified from CPV-, VV- or
SFV-infected cells.

AB Procainamide (PA) [51-06-9], an antiarrhythmic agent, was recently found
to be a specific inhibitor of suppressor T cells. The effects of PA and
x-ray irradiation were studied on both plaque forming cells (PFC) and antibody

titer using sheep red blood cells and vaccinia virus as antigens. A single injection of PA (50 µg) augmented both PFC and antibody titer; the increase was more than twice that seen after x-ray irradiation. A single injection of higher doses and repeated PA injections did not further augment antibody production. These data indicate that PA could be introduced as the sensitizing step in some exptl. antibody-dependent anticancer regimens.

Calcineurin and calcium/calmodulin-dependent protein kinase (CaMK) II have been suggested to be the signaling molecules in cardiac hypertrophy. It was not known, however, whether these mechanisms are involved in cardiac hypertrophy induced by pressure overload without the influences of blood-derived humoral factors, such as angiotensin II. To elucidate the roles of calcineurin and CaMK II in this situation, we examined the effects of calcineurin and CaMK II inhibitors on pressure overload-induced expression of c-fos, an immediate-early gene, and protein synthesis using heart perfusion model. The hearts isolated from Sprague-Dawley rats were perfused according to the Langendorff technique, and then subjected to the acute pressure overload by raising the perfusion pressure. The activation of calcineurin was evaluated by its complex formation with calmodulin and by its R-II phosphopeptide dephosphorylation. CaMK II activation was evaluated by its autophosphorylation. Expression of c-fos mRNA and rates of protein synthesis were measured by northern blot analysis and by ¹⁴C-phenylalanine incorporation, respectively. Acute pressure overload significantly increased calcineurin activity, CaMK II activity, c-fos expression and protein synthesis. Cyclosporin A and FK506, the calcineurin inhibitors, significantly inhibited the increases in both c-fos expression and protein synthesis. KN62, a CaMK II inhibitor, also significantly prevented the increase in protein synthesis, whereas it failed to affect the expression of c-fos. These results suggest that both calcineurin and CaMK II pathways are critical in the pressure overload-induced acceleration of protein synthesis, and that transcription of c-fos gene is regulated by calcineurin pathway but not by CaMK II pathway.

A total of 21 clones of acyclovir (ACV)-resistant (ACV(r)) herpes simplex virus type 1 (HSV-1) and 23 clones of penciclovir (PCV)-resistant (PCV(r)) HSV-1, emerging during serial passages in the presence of ACV or PCV, were isolated under conditions excluding contamination of resistant mutants in the starting virus culture, and their mutations in the thymidine kinase (TK) and DNA polymerase (DNA Pol) genes were analyzed comparatively. Mutations in the TK genes from ACV(r) mutants consisted of 50% single nucleotide substitutions and 50% frameshift mutations, while the corresponding figures for the PCV(r) mutants were 4 and 96%, respectively ($P < 0.001$). Eight of the 21 ACV(r) clones, but none of the 23 PCV(r) clones, had mutations in DNA Pol. Only nucleotide substitution(s) could be detected in the DNA Pol gene, as the gene is essential for virus replication. Therefore, the results for the DNA Pol mutants are concordant with those for the TK mutants in that a single nucleotide substitution was commonly observed in the ACV(r), but not in the PCV(r), mutants. These results clearly point to differential mutation patterns between ACV(r) and PCV(r) HSV-1 clones.

Collectins are a family of C-type lectins found in vertebrates. These proteins have four regions, a relatively short N-terminal region, a collagen-like region, an alpha-helical coiled coil, and a carbohydrate recognition domain. Collectins are involved in host defense through their ability to bind carbohydrate antigens on microorganisms. Type A scavenger receptors are classical-type scavenger receptors that also have

collagen-like domains. We previously described a new scavenger receptor, collectin from placenta [collectin placenta 1 (CL-P1)]. CL-P1 is a type II membrane protein with all four regions. We found that CL-P1 can bind and phagocytize both bacteria and yeast. In addition to that, it reacts with oxidized low-density lipoprotein (LDL) but not with acetylated LDL. These results suggest that CL-P1 might play important roles in host defenses and/or atherosclerosis formation. One rational strategy to study the role of CL-P1 in these pathological conditions would be to perform a haplotype association study using human samples. As a first step for this strategy, we analyzed the haplotype structure of the CL-P1 gene. By sequencing the CL-P1 gene in ten Japanese volunteers, we identified five single-nucleotide polymorphisms (SNPs) with a minor allele frequency of at least 29%. To obtain SNPs in the 5'-upstream region of the gene, we screened a total of 20 SNPs described in the database and finally picked up one SNP for the present study. Thus, a total of six SNPs, one in the 5'-upstream region, two in intron 2, one in exon 5, and two in exon 6, were used to analyze the haplotype structure of the gene, with DNAs derived from 54 individuals (108 alleles). The analysis revealed that only two of six SNPs showed significant linkage disequilibrium ($r^2 > 0.5$) with each other. This haplotype information may be useful in disease-association studies in which a contribution of the CL-P1 gene has been suspected, especially in immunological disturbance or atherosclerosis. Two SNPs in exon 6, both leading to amino acid substitutions, could be candidates for influencing disease susceptibility.

Collectins are members of the superfamily of vertebrate C-type lectins that contain a collagen-like region, and are involved in first-line host defense. We earlier cloned and characterized a new kind of collectin, collectin liver 1 (CL-L1). In this study, we isolated the mouse homologue of CL-L1 encoding 277 amino acid residues; its deduced protein sequence was 88% identical with human CL-L1. Mouse CL-L1 mRNA was expressed mainly in the liver and stomach, but was found also in muscles, testes, intestines, and embryos. In mouse embryos, the level of CL-L1 mRNA gradually increased with embryonic age. In 16-day-old mouse embryos, CL-L1 mRNA was expressed in the liver, amnion, and visceral yolk sac. The mouse CL-L1 gene, Cl11 was found on chromosome 15 in a region syntenic with human chromosome 8q. CL-L1 was a highly conserved protein in mammals, birds, and fish.

In response to oxidative stress, the pathogenesis of a number of cardiovascular events and several genes are stimulated by extracellular signal-regulated kinases (ERK1/2). Biphasic (early, 10 min; and delayed, 120 min) ERK1/2 activation by H(2)O(2), a reactive oxygen species, was observed in cultured neonatal rat cardiomyocytes. We investigated the hypothesis that the delayed activation of ERK1/2 depends on a factor secreted by oxidative stress (FSO). The delayed activation was inhibited by calphostin C, a protein kinase C inhibitor. Conditioned medium (CM) obtained from cells stimulated with H(2)O(2) induced rapid and monophasic ERK1/2 activation, which was not inhibited by calphostin C. In contrast, calphostin C-pretreated CM did not activate ERK1/2. Macrophage migration inhibitory factor (MIF) was one of the candidate FSOs activating ERK1/2. The existence of MIF in CM, the recombinant MIF-stimulated ERK1/2 rapid activation, and anti-MIF neutralizing antibody-induced inhibition of the delayed activation implied that MIF could be the FSO. Pretreatment of cardiomyocytes with a mitogen-activated protein kinase/ERK kinase (MEK) inhibitor did not suppress the MIF secretion, although it prevented the ERK1/2 activation by H(2)O(2). These results indicate that MIF is secreted from cardiomyocytes as a result of oxidative stress and activates ERK1/2 through a MEK1/2-dependent mechanism, although the secretion is not regulated by ERK1/2 but by protein kinase C.

Mannose binding lectin (MBL) binding initiates activation of the lectin complement pathway. Recent studies from our laboratory have demonstrated that MBL-dependent complement activation mediates cellular injury following oxidative stress in vivo and in vitro. A panel of novel inhibitory monoclonal antibodies (MAbs) against MBL (e.g., MAb 3F8, 2A9, and hMBL1.2) has been developed that inhibit MBL binding and lectin pathway activation. Here, we further characterized the interactions of these MAbs and their Fab fragments to MBL. Whole MAbs or their Fab fragments bound to MBL with

relatively high affinity. Fab fragments of 3F8 were functionally effective in inhibiting MBL-dependent complement activation, however, steric hindrance of MAb 2A9 was essential for inhibition of MBL-dependent complement activation. We identified the hinge region, and residues EDCVLLL within the carbohydrate recognition domain of MBL as the recognition sites for MAb 3F8 and 2A9, respectively. The interaction of MAbs (e.g., 3F8 and 2A9) to MBL was dependent on the conformation of their recognition sites. These findings demonstrate that MBL binding can be inhibited by at least two separate and independent mechanisms.

BACKGROUND/AIMS: The mannose-binding lectin (MBL) gene was reported to play an important role in determining the clinical outcome of persistent hepatitis B virus (HBV) infection. We investigated serum MBL concentrations and MBL gene mutations to determine whether they were related to the prognosis of patients with fulminant hepatic failure (FHF) caused by HBV infection. METHODS: We investigated serum MBL concentrations and MBL gene mutations in 43 HBV-infected Japanese patients with FHF and 260 HBsAg-negative healthy controls. Serum MBL concentrations were measured by an enzyme-linked immunosorbent assay, and mutations in the MBL gene were analysed by nested PCR and direct DNA sequencing. RESULTS: Only a mutation in codon 54 of the MBL gene was found. The frequency of this mutation in nonsurvivors (40%, 8/20) was higher than in survivors (13%, 3/23), and the difference was slightly significant ($p = 0.043$). The H allele frequency in survivors (70.5%, 31/44) was higher than in nonsurvivors (39.5%, 15/38) ($p = 0.0048$). Because of these factors the mean serum MBL concentration in survivors, 1.61 micro/ml (range 0.3-3.86), was significantly higher than in nonsurvivors, 0.79 microg/ml (range 0.04-1.51) ($p < 0.0001$). The likelihood ratio for nonsurvival was 0 for over 2.0 microg/ml, 0.67 for 1.0-2.0 microg/ml, and 2.24 for 0-1.0 microg/ml. CONCLUSIONS: The mutation in codon 54 of the MBL gene tended to be higher in nonsurvivors than in survivors. The H allele frequency (high producing allele in H/Y) in survivors was higher than that in nonsurvivors. High levels of serum MBL correlated with the survival of patients with FHF due to HBV infection. Serum MBL may be useful as a predictive factor for the survival of patients with FHF caused by HBV.

ABSTRACT: A recombinant conglutinin which contains a collagen region consisting of six amino acids containing two amino acid sequences Gly-Xaa-Xaa (SEQ ID NO:3, wherein Xaa stands for a protein-constituting amino acid), the neck region of natural conglutinin and the sugar chain recognition region of natural conglutinin, has an antiviral activity (virus neutralizing activity), and is expected to be applicable to drugs; and a process for detecting anti-influenza A virus activity of a mannose-binding protein (MBP) or a human mannose-binding protein (hMBP) involving the step of treating influenza A virus-infected cells with the MBP or hMBP and measuring the level of the suppression of the budding of the virus in the virus-infected cells. An MBP and an hMBP having an anti-influenza A virus activity are disclosed.

ABSTRACT: Collectins are a family of C-type lectins that have collagen-like sequences and carbohydrate recognition domains (CRD). They are involved in host defense through their ability to bind to carbohydrate antigens of microorganisms. The scavenger receptors type A and MARCO are classical type scavenger receptors that have internal collagen-like domains. Here we describe a new scavenger receptor that is a membrane-type collectin from placenta (collectin placenta 1 (CL-P1)), which has a typical collectin collagen-like domain and a CRD. The cDNA has an insert of about 2.2 kilobases coding for a protein containing 742 amino acid residues. The deduced amino acid sequence shows that CL-P1 is a type II membrane protein, has a coiled-coil region, a collagen-like domain, and a CRD. It resembles type A scavenger receptors because the scavenger receptor cysteine-rich domain is replaced by a CRD. Northern analyses, reverse transcription-polymerase chain reaction, and immunohistochemistry show that CL-P1 is expressed in vascular endothelial cells but not in macrophages. By immunoblotting and flow cytometry CL-P1 appears to be a

membrane glycoprotein of about 140 kDa in human umbilical vein or arterial endothelial cells, placental membrane extracts, and CL-P1 transfected Chinese hamster ovary cells. We found that CL-P1 can bind and phagocytose not only bacteria (*Escherichia coli* and *Staphylococcus aureus*) but also yeast (*Saccharomyces cerevisiae*). Furthermore, it reacts with oxidized low density lipoprotein (OxLDL) but not with acetylated LDL (AcLDL). These binding activities are inhibited by polyanionic ligands (polyinosinic acid, polyguanylic acid, dextran sulfate) and OxLDL but not by polycationic ligands (polyadenylic acid or polycytidylic acid), LDL, or AcLDL. These results indicate that CL-P1 might play important roles in host defenses that are different from those of soluble collectins in innate immunity.

ABSTRACT: Mannan-binding lectin (MBL) constitutes an important part of the innate immune defence by effecting the deposition of complement on microbial surfaces. MBL deficiency is among the most common primary immunodeficiencies and is associated with recurrent infections and symptoms of poor immune complex clearance. Plasma-derived MBL has been used in reconstitution therapy but concerns over viral contamination and production capacity point to recombinant MBL (rMBL) as a future source of this protein for clinical use. Natural human MBL is an oligomer of up to 18 identical polypeptide chains. The synthesis of rMBL has been accomplished in several mammalian cell lines, however, the recombinant protein differed structurally from natural MBL. In this, study we compare rMBL produced in myeloma cells, Chinese hamster ovary (CHO) cells, human hepatocytes, and human embryonic kidney (HEK) cells. We report that rMBL structurally and functionally similar to natural MBL can be obtained through synthesis in the human embryonic kidney cells followed by selective carbohydrate affinity chromatography.

ABSTRACT: Fab fragments of a wild type or mutants of an
anti-(4-hydroxy-3-nitrophenyl)acetyl mAb, B2, were expressed on the
surface of a filamentous phage in order to examine the role of conserved
amino acid residues at positions 32, 50, and 60 in complementarity
determining regions. These had been predicted previously as
specificity-determining residues (Taketani et al., 1995, Molec. Immunol.,
32:983). Phages expressing mutant Fabs with replacement of a single amino
acid at these positions in complementarity determining regions of the
heavy-chain V region showed a large to complete loss of ability to bind
haptens. In addition, substitution of Tyr60 hindered formation of Fab,
suggesting that this amino acid residue is critical for the interaction
between V domains in heavy and light chains. Thus, the amino acid
residues conserved in somatic mutation of complementarity determining
regions are important in determining Ab-specificity as well as in inter-V
domain interactions.

ABSTRACT: Collectins are a C-lectin family with collagen-like sequences and
carbohydrate recognition domains. These proteins can bind to carbohydrate
antigens of microorganisms and inhibit their infection by direct
neutralization and agglutination, the activation of complement through
the lectin pathway, and opsonization by collectin receptors. Here we
report the cloning of a cDNA encoding human collectin from liver (CL-L1
(collectin liver 1)) that has typical collectin structural
characteristics, consisting of an N-terminal cysteine-rich domain, a
collagen-like domain, a neck domain, and a carbohydrate recognition
domain. The cDNA has an insert of 831 base pairs coding for a protein of
277 amino acid residues. The deduced amino acid sequence shows that this
collectin has a unique repeat of four lysine residues in its C-terminal
area. Northern blot, Western blot, and reverse transcription-polymerase
chain reaction analyses showed that CL-L1 is present mainly in liver as a
cytosolic protein and at low levels in placenta. More sensitive analyses
by reverse transcription-polymerase chain reactions showed that most

tissues (except skeletal muscle) have CL-L1 mRNA. Zoo-blot analysis indicated that CL-L1 is limited to mammals and birds. A chromosomal localization study indicated that the CL-L1 gene localizes to chromosome 8q23-q24.1, different from chromosome 10 of other human collectin genes. Expression studies of fusion proteins lacking the collagen and N-terminal domains produced in *Escherichia coli* affirmed that CL-L1 binds mannose weakly. CL-L1 and recombinant CL-L1 fusion proteins do not bind to mannan columns. Analysis of the phylogenetic tree of CL-L1 and other collectins indicated that CL-L1 belongs to a fourth subfamily of collectins following the mannan-binding protein, surfactant protein A, and surfactant protein D subfamilies including bovine conglutinin and collectin-43 (CL-43). These findings indicate that CL-L1 may be involved in different biological functions.

ABSTRACT: We have developed a high-expression system of recombinant human mannan-binding lectin (MBL) with CHO cells. Geneticin-resistant transformants harboring human MBL cDNA in the expression vector pNOW/CMV-A were screened by immunoblot analysis for secretion of recombinant MBL. Cloning and selection by both geneticin and methotrexate resulted in the production of recombinant MBL to a final concentration of 128.8 mug/ml in media after four days of culture. SDS-PAGE and gel-filtration analyses showed that recombinant MBL is characterized by two lower-order oligomeric structures (apparent molecular weights: 1150 kDa and 300 kDa) compared to native MBL (apparent molecular weight: 1300 kDa). The recombinant human MBL has both sugar-binding and complement activation activity and, like native MBL, can inhibit hemagglutination of influenza A virus. Lectin blots with recombinant MBL indicate that it can bind such microorganisms as HIV and influenza virus suggesting that it might inhibit their infection of hosts. This high-level expression of human MBL with the full range of biological activity will be useful for studies on the immunological role of MBL in humans.

ABSTRACT: Mannan-binding protein (MBP) is a calcium-dependent mammalian serum lectin important in first-line host defense. MBP belongs to the collectin family, which is characterized by an NH₂-terminal cysteine-rich domain, a collagen-like domain, a neck domain, and a carbohydrate recognition domain (CRD). We have expressed a recombinant human MBP, consisting of the short collagen region (two repeats of Gly-Xaa-Yaa amino acid sequences), the neck domain, and the CRD, in *Escherichia coli*. The truncated MBP was capable of forming trimers by association of the neck domain and could bind sugar with a specificity similar to that of the native form. Results of hemagglutination inhibition (HI) assay of influenza A virus showed that the truncated MBP inhibited hemagglutination less strongly, although the native MBP induced the HI phenomenon. These results suggest that an oligomeric structure is an advantage for MBP to have full biological activity against influenza A virus.

ABSTRACT: Mannan-binding protein (MBP) is a member of the collectin family of protein. There are two types of MBP, MBP-A and MBP-C, which were found in rodent (rats and mice), rhesus monkey, and cynomolgus monkey, while chimpanzee and human have only one MBP. It was considered that the loss of one MBP gene occurred during hominoid evolution. In this article two rabbit MBP, a liver and serum MBP, were characterized biologically and genetically. Analyses by SDS-PAGE under reduced condition and their amino acid sequences of both MBPs showed that they have a same molecular weight of 32 kDa and their amino acid sequences were identical. A serum MBP has a higher ability to activate complement than does a liver MBP; however, a liver MBP inhibits hemagglutination by influenza virus as strongly as a serum MBP does. cDNA clones encoding the rabbit MBP were isolated from a rabbit cDNA liver library using whole cDNA of mouse MBP-C as a probe. The cDNA carried an insert of 744 bp coding for a protein of 247 acid residues with a signal peptide of 22 residues. The deduced amino acid sequence of the cDNA was identical to that of amino acid sequences of the 32 kDa proteins determined here. Northern blot analysis showed that mRNA

transcripts of about 0.9 and 3.0 kb were expressed only in the liver. The analysis of the phylogenetic tree of rabbit and bovine MBPs and other collectins indicates that the loss of MBP gene occurred not only during hominoid evolution but also at some points after the separation of birds and mammals.

ABSTRACT: We describe here the successful expression of recombinant bovine conglutinin in CHO cells as well as its physical and biological characteristics. Geneticin-resistant transformants harboring bovine conglutinin cDNA in the expression vector pNOW/CMV-A were screened by Western blot analysis for secretion into media of recombinant conglutinin. A four-day amplification of the transgene with increasing concentrations of methotrexate resulted in a dose-dependent increase in the production of recombinant conglutinin to a final concentration of 18.6 μ -g/ml of media. Recombinant conglutinin purified from this media by affinity column chromatography on mannan-agarose had a migration pattern similar to that of native conglutinin on polyacrylamide gel electrophoresis under reducing, nonreducing, and native conditions. The recombinant conglutinin exhibited sugar binding, conglutination, hemagglutination inhibition, and neutralization of influenza A virus, activities engaged in by the native conglutinin. This is the first report describing a high level of expression of a serum cruciform collectin with the full range of biological activity.

ABSTRACT: Surfactant protein D (SP-D) is a lung-specific protein that is synthesized and secreted by lung epithelial cells and is believed to play an important role in lung host defence. This protein belongs to the C-type lectin family, which is characterized by an N-terminal cysteine-rich domain, a collagen-like domain, a neck domain and a carbohydrate recognition domain (CRD). To elucidate the biological actions of this animal lectin against such pathogens as micro-organisms, the biological activities of a recombinant partial SP-D lacking a collagen-like domain were examined. A recombinant human SP-D, consisting of a short collagen region (two repeats of Gly-Xaa-Yaa amino acid sequences), the neck domain and the CRD, was expressed in *Escherichia coli*. The recombinant SP-D was purified on a nickel column and then on a maltose-agarose column. This protein can form a trimeric structure owing to the neck domain and exhibits sugar-binding activity and specificity similar to those of native human SP-D. The recombinant SP-D caused dose-dependent and calcium-dependent agglutination of *E. coli* Y1088. The agglutination titre (the concentration required to achieve a 50% decrease in light transmission by agglutination) of recombinant SP-D was approx. 6-fold that of native SP-D. As for conglutination, the recombinant trimeric conglutinin required 8-16-fold higher concentrations than the native counterpart. In haemagglutination inhibition (HI) of influenza A virus, although native and recombinant conglutinin showed similar levels of HI activity, the recombinant SP-D was unable to inhibit haemagglutination, even at a concentration approx. 120-fold that of the native SP-D. The lectin precipitation and lectin blot assays showed that the truncated SP-D could bind to influenza A virus as well as native SP-D did. These results indicate that the agglutination activity of trimeric collections can be largely retained, and furthermore that the oligomeric structure with several hands at opposite sites can enhance agglutination activity. The difference in HI activity against influenza A virus between native and recombinant SP-D suggests that SP-D uses a different mechanism from that of conglutinin to inhibit viral haemagglutination.

ABSTRACT: To identify the bovine mannan-binding protein (MBP), a search for the cDNA homologue of human MBP was carried out. cDNA clones encoding bovine MBP were isolated from a bovine liver cDNA library using a cDNA fragment encoding a short collagen region, neck domain and carbohydrate recognition domain of human MBP. The cDNA carried an insert of 747 bp encoding a protein of 249 amino acid (aa) residues with a signal peptide of 19 aa. The mannan-binding protein fraction of bovine serum that eluted with 100 mM mannose from a mannan-Sepharose column was analyzed under reducing conditions by SDS-PAGE. The major band of 33 kDa obtained reacted with anti-human MBP rabbit serum. The partial aa sequence of the purified 33-kDa protein was identical to the aa sequence deduced from the obtained cDNA. Results of the passive hemolysis experiment using sheep

erythrocytes coated with yeast mannan suggest that this MBP has the ability to activate complement. Northern blot analysis showed a 1.8-kb mRNA that was expressed only in the liver. Based on results of genomic analysis, this bovine MBP is likely to be a homologue of human MBP and to also have homology to rat and mouse MBP-C which are localized in liver cells rather than to rat and mouse MBP-A found in serum. Alignments of bovine collectins show that bovine MBP cannot be included among the other bovine collectins, such as bovine SP-D, conglutinin and CL-43. Finally, these genomic and biological analyses indicate that the cDNA obtained here encoded a bovine serum MBP.

ABSTRACT: Feline immunodeficiency virus (FIV) infection in cats has been reported to be a useful animal model for human AIDS studies, especially in the early stages of infection. We examined the temporal changes in provirus detection in peripheral blood mononuclear cells (PBMC) and the distribution of FIV-DNA and RNA in feline tissues by the polymerase chain reaction at 10, 35, 70 days after intravenous inoculation of FIV. Viral DNA in the PBMC was detected three to four weeks after infection and its fluctuation was demonstrated for the first time. Ten days after infection, before seroconversion, proviruses were detected only in the mesenteric lymph nodes and intestines. At 35 and 70 days after infection, after seroconversion, proviruses were detected in most lymphoid organs and the salivary glands, but the expression of FIV-RNA was limited to the thymus at 70 days after infection. These results show that FIV-RNA is transcribed from proviral DNA exclusively in the thymus at this stage. We suggest that the quantitative changes in detectable proviruses in the PBMC depend on the relation between the decrease in infected cells caused by cytolytic T lymphocytes and/or apoptosis and their increase caused by the release of a new supply of lymphocytes from the thymus.

ABSTRACT: Levels and catalytic activities of cytochrome P450 (P450) enzymes involved in the oxidation of drugs and carcinogens were determined in human adult lungs and fetal livers and compared with those in microsomes from adult livers. P450s immunoreactive with anti-human P4501A1 and anti-human P4503A antibodies were detected in fetal liver microsomes by immunoblotting analysis, and P450s related to P4501A1, 2A6, 2C9, 2E1, and 3A4 were determined in adult lung microsomes; all of these P450 enzymes were detected in much higher amounts in adult liver microsomes except that P4501A2 was only the 1A subfamily of P450 found in adult livers. Drug oxidation activities with the substrates ethoxyresorufin, coumarin, 7-ethoxycoumarin, bufuralol, and testosterone were determined in these microsomes, and we found that none of the activities were higher in microsomes of adult lungs and fetal livers than in adult livers. Activation of procarcinogens to reactive metabolites that induce umu gene expression in *Salmonella typhimurium* TA1535/pSK1002 or NM2009 was also examined and it was found that activities with (+)- and (-)-enantiomers of 7,8-dihydroxy-7,8-dihydrobenzo(a)pyrene were higher in fetal liver microsomes than adult lung or liver microsomes. The adult liver and lung activities for these two procarcinogens were similar on the microsomal protein contents despite the facts that P450 contents are higher in liver than lung microsomes. α -Naphthoflavone, a known inhibitor of P4501A-related activities, did not affect these procarcinogen activation in fetal liver microsomes. Fetal liver microsomes catalyzed activation of aflatoxin B-1 and sterigmatocystin, two procarcinogens known to be activated by P4503A4/7 in humans, although activation of carcinogenic arylamines that are good substrates for P4501A2 was much lower in microsomes of fetal livers and adult lungs than in adult livers. These results suggest that in human fetal livers at least two P450 enzymes, a form of P450 that is immunoreactive to P4501A1 and P4503A7, are actually expressed and these enzymes are suggested as being involved in the activation of the (+)- and (-)-enantiomers of 7,8-dihydroxy-7,8-dihydrobenzo(a)pyrene and the carcinogenic mycotoxins, respectively. The exact nature of the former enzyme in fetal livers is unknown. In adult human lungs, several P450 enzymes are expressed, although the precise roles of these enzymes in the oxidation of xenobiotics were not determined due to the low level of expression of these P450s.

Recombinant bovine conglutinin, lacking the N-terminal and collagenous domains, has less conglutination activity but is able to inhibit haemagglutination by influenza A virus

ABSTRACT: Conglutinin is a bovine serum protein which was first described as a vertebrate lectin. This protein belongs to the family of C-type lectins. These lectins are composed of four characteristic domains: (1) an N-terminal cysteine-rich domain, (2) a collagen-like domain, (3) a neck domain and (4) a carbohydrate recognition domain (CRD). Recently lectins have been shown to function as immunoglobulin-independent defence molecules due to a complement-mediated mechanism or opsonization. Our previous study showed that bovine conglutinin can inhibit haemagglutination by influenza A viruses and act by directly neutralizing them due to its lectin properties. In order to elucidate the biological role of the collagen-like domain, a recombinant partial conglutinin lacking this collagen-like domain was produced in an *Escherichia coli* system and its biological activities were examined. A 497 bp sequence, consisting of a short collagen region (two repeats of G-X-Y amino acid sequences), the neck domain, and the CRD of conglutinin cDNA, was amplified by the reverse-transcriptase PCR technique. The cDNA was transferred to a bacterial expression vector system (pRSET-A) and stable transfectants with a high level of conglutinin production were obtained. SDS/PAGE and Western blotting analyses showed a recombinant fusion protein of 27 kDa. Results of a cross-linking study and gel-filtration assay indicated that the recombinant conglutinin can form a trimeric structure and that it has sugar binding activity and specificity similar to that of native conglutinin. The recombinant conglutinin was also found to inhibit haemagglutination caused by influenza A virus as well as to possess less conglutination activity. These results suggest that in order for conglutinin to inhibit haemagglutination caused by the influenza virus, as well as to have sugar binding activity or to form trimers, it does not require the N-terminal and collagenous domains; however, they are essential for full conglutination activity.

ABSTRACT: We have measured glycosyltransferase activities of SupT1 cells, a T-lymphoid cell line shown to react with autoantibodies in the sera of many HIV patients. Since considerable alpha-N-acetylgalactosaminyl-transferase and beta-1,3 galactosyltransferase activities were found in SupT1 cells, at least the O-glycan core 1 structure can probably be synthesized. FACS analysis using an anti-T monoclonal antibody showed expression of the T antigen (Gal beta-1-3 GalNAc). Glycoproteins with the T antigen were isolated by immunoprecipitation with the anti-T antibody from a SupT1 cell lysate labelled metabolically with 3H-glucosamine and then analysed by SDS-PAGE. It was revealed that the precipitate contained a glycoprotein with a molecular weight corresponding to that of leukosialin. O-glycans were prepared from the immunoprecipitate by alkaline-borohydride treatment and then fractionated on Bio-Gel P-2, GalNAcOH and Gal-GalNAcOH being identified inter alia. These results suggest that an anti-T antibody may be included in the autoantibodies found in HIV-1 infected individuals.

ABSTRACT: The anti-tumor activity of 7 sphingolipids, 2 ceramides and 5 glycosphingolipids against the syngeneic murine ascitic tumors MH134 and MM102 in C3H mice was examined. Five of these compounds showed anti-tumor activity against the tumours, ceramide type-IV (Cer-IV) having the highest activity without cytotoxic or cytostatic activity. These results indicate that the fatty acid in ceramide and sugar chains binding to it affect the anti-tumor activity in vivo. The anti-tumor activity of Cer-IV depended on the time of treatment. Mice treated with Cer-IV one day after tumor implantation showed the highest rate of survival. The cured mice were resistant to rechallenge with the same tumor (MH134 fwdarw MH134, MM102 fwdarw MM102) but not with a heterologous tumor (MH134 fwdarw X5563, MM102 fwdarw X5563), indicating that the effect of Cer-IV may be due to in vivo induction of specific immunity. Studies with various antibodies demonstrated that the anti-tumor effect of Cer-IV was inhibited by all the antibodies tested (L3T4, Lyt-2, and Thy-1,2 T cells, macrophages, and TNF-alpha) in the induction phase (before Cer-IV administration) and by the antibodies of L3T4 and TNF-alpha in the effector phase (after Cer-IV administration). Therefore, the anti-tumor effect of Cer-IV in this system depended on the host immune response rather than on its direct cytotoxic and/or cytostatic action.

ABSTRACT: A 912 bp bovine cDNA fragment encoding bovine conglutinin was amplified by the RT-PCR technique. cDNA clones encoding the bovine conglutinin were isolated from a bovine liver cDNA library using a specific probe obtained from the PCR product. These cDNAs carry an insert of 1113 bp coding for a protein of 371 amino acid residues with a signal

peptide of 20 residues. The deduced amino acid sequence of cDNA agrees with that determined by conventional amino acid sequence analysis. Two polyadenylation signal sequences were detected in the DNA sequence downstream of the 3' end of the gene. Southern blot analysis of total bovine genomic DNA indicated that there is only one copy of the gene encoding bovine conglutinin. Northern blot analysis of bovine tissues showed that conglutinin mRNA of about 1.5 kb is expressed in the liver and also slightly in the lung.

ABSTRACT: As the majority of human immunodeficiency virus (HIV) carriers are in asymptomatic stage for a long period of time, it is important to investigate the factors or surrogate markers for conversion from asymptomatic to symptomatic stage. Our study is designed to evaluate the relationship among virus isolation rate, anti-pl7 antibody status and progression to AIDS. We studied anti-pl7 antibody status along with virus isolation in 56 asymptomatic carriers and 46 AIDS cases. Progression to AIDS was markedly associated with high rate of virus isolation and loss of anti-pl7 antibody. In order to know the meaning of loss of anti-pl7 antibody during the clinical course, 15 anti-pl7 antibody positive and 16 anti-pl7 antibody negative cases were followed up prospectively for the development of AIDS. None of the anti-pl7 antibody positive cases developed AIDS while 6 out of 15 anti-pl7 negative cases developed AIDS during observation period (P lt 0.05). Progress to AIDS was associated with loss of anti-pl7 antibody. Identification of cases losing anti-pl7 antibody in peripheral blood during asymptomatic period may help, identify a high-risk group who are in need of chemoprophylaxis. Moreover, study of anti-pl7 antibody may be helpful in designing vaccine in the future if it works as a neutralizing antibody to HIV in vivo.

ABSTRACT: Normal horse and guinea pig sera contain alpha-2-macroglobulin which inhibits the infectivity and hemagglutinating activity of influenza A viruses of the H2 and H3 subtypes. On the other hand, normal bovine serum contains a component termed beta inhibitor that inhibits the infectivity and hemagglutinating activity of influenza A viruses of the H1 and H3 subtypes. To investigate the nature of the beta inhibitor of influenza A virus, we purified the conglutinin and examined its characteristics. First, we found a high correlation between the hemagglutination inhibition(HI) titer and conglutinin titer in several bovine sera($r = 0.906$, $p < 0.005$). The HI of bovine serum was mainly dependent on conglutinin because the HI activity was abrogated by N-acetylglucosamine but not by D-mannose. The conglutinin, purified from bovine serum, had neutralizing-activity as well as HI activity on influenza A viruses of the H1 and H3 subtypes. The HI activity of conglutinin was heat stable(56 degree C, 30 min), Ca^{++} -dependent, and resistant to both neuraminidase and periodate treatments. The HI activity of purified conglutinin was blocked by N-acetylglucosamine but not by D-mannose. The conglutinin was bound to hemagglutinin which had high mannose and complex sugar chains and its binding was inhibited by N-acetylglucosamine and dependent on divalent cations. These data indicate that the beta-like inhibitor activity of bovine serum is mainly dependent on conglutinin which inhibits hemagglutination and neutralizes the virus infectivity by its binding to a carbohydrate site at the HA.

ABSTRACT: The MBL polymorphism was investigated in the anti-RNP
antibody-positive patients and autoimmune patients. For this reason,
the genomic DNA was prepared from the patient blood, and the
polymorphism of codon 54 of the MBL gene was decided by the PCR-RFLP
method. Among 54 patients, there were 29 normal-type homozygotes(AA),
16 heterozygotes(AB), and 3 minority-type homozygotes(BB); the
frequency of the B allele was 20.4%.The blood AB concentration was
significantly lower in the AB patients than that in the AA patients,
and was further lowered in the BB patients. Of 18 patients with the B
allele, the infectious disease requiring hospitalization was recognized
in 6 patients during the course; this tended to be a little abundant as
compared with 7 out of 33 persons without the B allele. The clear
relation is not observed between visceral lesions such as pulmonary
hypertension and the MBL gene polymorphism.

ABSTRACT: It focused on the capillary endothelium, and the research of the biophylaxis system by lectin was advanced. Gene cloning of new lectin CL-P1 and genetic analysis experiment with it were almost completed in the first year, and establishment of the eternal expression cell for the functional analysis and mouse genomic gene analysis for knockout mouse advanced. And, the phylaxis action on malaria and AIDS virus was also discovered in the functional analysis.

ABSTRACT: The monoclonal antibody of mannan binding protein (MBP) was made, and the recognition site of the complement activation antibody was examined. The position which related to the lectin dependence complement activation activity interference of the MBP was clarified. The influenza virus infection experiment was carried out in the system of mouse and hamster, and the physiological role of the MBP was examined. Animal experiment model in the decision of the MBP phylaxis effect was able to be made. The following were examined : MBP change in the stress in the human and gene polymorphism of the MBP in various diseases. The effect of the recombinant MBP was examined in HIV type C type stock in which the neutralizing antibody was difficult to work. It was clarified that the MBP caused the neutralization in the HIV stock in which the neutralizing antibody does not demonstrate the effect.

ABSTRACT: It became clear that the serum MBP concentration showed the high value by the measurement in the Hansen's disease patient in respect of serum MBP (animal serum lectin) concentration of the MHansen's disease patient of Japan and Indonesia. Animal serum lectin reported until now and relevance to the adid-fast organism were analyzed in order to clarify the mechanism in which the high value of such serum MBP promotes the adid-fast organism infection. Then, MBP concentration measurements were carried out of the various diseases that the compromised host was suspected, and MBP high value was recognized in the hemodialysis patient. It was guessed that there were high infectiousness and relevance in the hemodialysis patient on this fact.

ABSTRACT: Collectins belong to a subfamily of C type lectins, and have the collagen-like structure and the sugar recognition domain in their intramolecular structures. Among the collectins, mannose binding lectin(MBL) found as a secretory type in serum, conglutinin(BKg), collectin 43(CL-43), surfactant protein A(SP-A), surfactant protein D(SP-D), and collectin liver1(CL-L1) have been reported so far. This paper describes the structural characteristics, and biological properties of these collectins.

ABSTRACT: Carriers of HIV-1(A) positive in a peripheral blood were summed
up from 1987 to 1995, and the results were examined. The test for
detection of A was performed on about 300 blood samples every year.
Almost all samples were from Japanese hemophilia patients infected with
A. The results of the test were correlated with the progress of the
disease with A infection.

Journal: Hybridoma, 2002, 21 (1) 25-36

Language: English

Mannose binding lectin (MBL) binding initiates activation of the lectin complement pathway. Recent studies from our laboratory have demonstrated that MBL-dependent complement activation mediates cellular injury following oxidative stress in vivo and in vitro. A panel of novel inhibitory monoclonal antibodies (MAbs) against MBL (e.g., MAb 3F8, 2A9, and hMBL1.2) has been developed that inhibit MBL binding and lectin pathway activation. Here, we further characterized the interactions of these MAbs and their Fab fragments to MBL. Whole MAbs or their Fab fragments bound to MBL with relatively high affinity. Fab fragments of 3F8 were functionally effective in inhibiting MBL-dependent complement activation, however, steric hindrance of MAb 2A9 was essential for inhibition of MBL-dependent complement activation. We identified the hinge region, and residues EDCVLLL within the carbohydrate recognition domain of MBL as the recognition sites for MAb 3F8 and 2A9, respectively. The interaction of MAbs (e.g., 3F8 and 2A9) to MBL was dependent on the conformation of their recognition sites. These findings demonstrate that MBL binding can be inhibited by at least two separate and independent mechanisms.

Title: Recombinant conglutinin and process for producing the same.

AUTHOR: **Wakamiya, Nobutaka**

CORPORATE SOURCE: Fuso Pharm. Ind. Ltd. Osaka 541 Japan

CODEN: EPXXDW

PATENT NUMBER: EP 856580

PUBLICATION DATE: 5 Aug 1998 (980805) LANGUAGE: English

PRIORITY PATENT APPLICATION(S) & DATE(S): JP 20969895 (950817)

ABSTRACT: A recombinant conglutinin is disclosed which contains a collagen region consisting of 6 amino acids containing 2 amino acid sequences Gly-Xaa-Xaa, in which Xaa stands for a protein-constituting amino acid, the neck region of natural conglutinin, and the sugar chain-recognition region of natural conglutinin. It has an antiviral activity (virus-neutralizing activity). Also disclosed is a process for detecting the anti-influenza A virus activity of a mannose-binding protein (MBP) or a human mannose-binding protein (hMBP) involving the step of treating influenza A virus-infected cells with the MBP or hMBP, and measuring the level of the suppression of the budding of the virus in the virus-infected cells. An MBP and an hMBP having anti-influenza A virus activity are also disclosed.

Abstract: Recombinant Human Mannan-Binding Proteins (rhMBP) having physiological activities which are substantially identical to those offered by Human Mannan-Binding Proteins (hMBP), as well as, in particular, a production system for homogenously producing rhMBP having the specific peaks at the molecular weight of 1,000*1,300 kDa determined by absorbance (280 nm) in Gel-Filtration Chromatography are provided.

Abstract: Novel scavenger receptors having an SR structure and a collectinlike structure are provided, which can be utilized in the elucidation of mechanisms of macrophage and basic immunity; in the elucidation of mechanisms of the development of a wide variety of diseases

such as arteriosclerosis, diabetic complications and Alzheimer's disease, hyper beta lipoproteinemia, hypercholesterolemia, hypertriglyceridemia, hypo alpha -lipoproteinemia, transplantation, atherectomy, post angiogenic restenosis, bacterial infections; in the diagnostic, prophylactic and therapeutic methods thereof; and in the development of reagents and drugs for the same. The novel scavenger receptors include proteins comprising an amino acid sequence set out in SEQ ID NO: 2, 4 or 24 or proteins having equivalent properties to the same, or derivatives or fragments thereof as well as isolated polynucleotides comprising a nucleotide sequence encoding these proteins, and related molecules such as antibodies, antagonists and the like. Also disclosed are methods for the treatment using the same.

RECOMBINANT HUMAN MANNAN BINDING PROTEIN AND ITS PRODUCTION

PUB. NO.: 11-206378 [JP 11206378 A]
 PUBLISHED: August 03, 1999 (19990803)
 INVENTOR(s): **WAKAMIYA NOBUTAKA**
 APPLICANT(s): FUSO PHARMACEUTICAL INDUSTRIES LTD
 APPL. NO.: 10-011864 [JP 9811864]
 FILED: January 23, 1998 (19980123)

ABSTRACT

PROBLEM TO BE SOLVED: To provide a system for homogeneously producing a recombinant human mannan binding protein (rhMBP) having the same physiological activity as that of human mannan binding protein (hMBP).

SOLUTION: A portion of 66 bp to 812 bp in the cDNA of a native human mannan binding protein (native hMBP) is sectioned and then inserted into an expression vector pNOW1 to construct an expression vector pNOW1-hMBP, which, in turn, is transferred into dihydrofolic acid reductanase-deficient (dhfr-) Chinese hamster ovarian(CHO) cells to afford the corresponding transformant, which is then cultured in a neomycin-contg. medium to produce neomycin-resistant cells, which, in turn, is cultured in a medium containing methotrexate(MTX) to afford MTX-resistant cells, from which the aimed rhMBP is recovered, being such that the absorbance at 280 nm when treated with gel filtration chromatography represents a specified peak with a molecular weight of 1,000-1,300 kDa.

NEW COLLECTIN

PUB. NO.: 11-206377 [JP 11206377 A]
 PUBLISHED: August 03, 1999 (19990803)
 INVENTOR(s): **WAKAMIYA NOBUTAKA**
 APPLICANT(s): FUSO PHARMACEUTICAL INDUSTRIES LTD

APPL. NO.: 10-011281 [JP 9811281]
FILED: January 23, 1998 (19980123)

ABSTRACT

PROBLEM TO BE SOLVED: To obtain a polynucleotide encoding a new collectin which exhibits antibacterial, antiviral activity or the like in vivo in humans and is useful as a physiologically active medicinal substance.

SOLUTION: This polynucleotide contains a base sequence encoding a protein constituted of an amino acid sequence of the formula. This polynucleotide is obtained by the following procedure: regions with higher preservability among known collections are retrieved, an EST database is retrieved to afford data (registry number: R 29493) containing unknown base sequences; from a clone as the base of the above data, a probe for screening use is prepared; a human liver-derived cDNA library subjected to titration is screened with the probe, a positive clone is subjected to secondary screening in a similar way, the base sequence of the whole region of the plasmid of a transformant afforded by transformation with a DNA fragment based on the resulting positive clone is determined, thus obtaining the aimed cDNA clone encoding the amino acid sequence of the formula.

ABSTRACT EP 1283214 A1

Provided are isolated collectin (CL-L2s) genes including a base
sequence set out in SEQ ID NO: 1, 3, 5, 7, 9, 12, 36, 38 or 40 relating
to a novel collectin which are expected to exhibit an antibacterial
activity, an antiviral activity and the like particularly in a human
body; and isolated collectin proteins including an amino acid sequence
set out in SEQ ID NO: 2, 4, 6, 8, 10, 13, 37, 39 or 41 and derivatives
and fragments thereof.

ABSTRACT EP 1262546 A1

Novel scavenger receptors having an SR structure and a collectin-like structure are provided, which can be utilized in the elucidation of mechanisms of macrophage and basic immunity; in the elucidation of mechanisms of the development of a wide variety of diseases such as arteriosclerosis, diabetic complications and Alzheimer's disease, hyper (beta)-lipoproteinemia, hypercholesterolemia, hypertriglyceridemia, hypo (alpha)-lipoproteinemia, transplantation, atherectomy, post angiogenic restenosis, bacterial infections; in the diagnostic, prophylactic and therapeutic methods thereof; and in the development of reagents and drugs for the same. The novel scavenger receptors include proteins comprising an amino acid sequence set out in SEQ ID NO: 2, 4 or 24 or proteins having equivalent properties to the same, or derivatives or fragments thereof as well as isolated polynucleotides comprising a nucleotide sequence encoding these proteins, and related molecules such as antibodies, antagonists and the like. Also disclosed are methods for the treatment using the same.

ABSTRACT EP 856580 A1

A recombinant conglutinin which contains a collagen region consisting of six amino acids containing two amino acid sequences Gly-Xaa-Xaa (SEQ ID NO:3, wherein Xaa stands for a protein-constituting amino acid), the neck region of natural conglutinin and the sugar chain recognition region of natural conglutinin, has an antiviral activity (virus neutralizing activity), and is expected to be applicable to drugs; and a process for

detecting anti-influenza A virus activity of a mannose-binding protein (MBP) or a human mannose-binding protein (hMBP) involving the step of treating influenza A virus-infected cells with the MBP or hMBP and measuring the level of the suppression of the budding of the virus in the virus-infected cells. An MBP and an hMBP having an anti-influenza A virus activity are disclosed.

ABSTRACT EP 846701 A1

A recombinant conglutinin containing a collagen region comprising six amino acid residues containing two amino acid sequences Gly-Xaa-Xaa (SEQ ID NO:3, Xaa representing a protein-constituting amino acid residue), a neck region of natural conglutinin and a sugar-chain recognition region of natural conglutinin, having an antiviral activity (neutralizing activity), and being expected to be applicable for medicinal uses.

English Abstract

It is intended to disclose an anti-HIV agent which contains as the active ingredient a mannose-binding protein (MBP) and efficaciously contributes to the treatment of patients infected with human immunodeficiency virus (HIV) and inhibits the progress of the disease. It is also intended to disclose a method of evaluating an anti-HIV activity exerted by the MBP which involves the step of culturing HIV-infected cells in the presence of the MBP.

French Abstract

Cette invention concerne un agent anti-HIV qui contient comme principe actif une proteine de fixation du mannose (MBP) et qui contribue efficacement au traitement de patients infectes par le virus de l'immunodeficiency humaine (HIV) et inhibe la progression de la maladie. Cette invention concerne egalement un procede servant a evaluer l'activite anti-HIV de la proteine MBP, ce procede consistant a cultiver des cellules infectees par le virus HIV en presence de la proteine MBP.

English Abstract

Isolated collectin (CL-L2s) genes containing a base sequence represented
by SEQ ID NO:1, 3, 5, 7, 9, 12, 36, 38 or 40 relating to novel collectins
which are expected as exhibiting an antibacterial activity, an antiviral
activity, etc. particularly in the human body; and isolated collectin
proteins containing an amino acid sequence represented by SEQ ID NO:2, 4,
6, 8, 10, 13, 37, 39 or 41 and derivatives and fragments thereof.

French Abstract

L'invention concerne des genes de collectine (CL-L2S) isolees contenant
une sequence de base representee par SEQ ID NO:1, 3, 5, 7, 9, 12, 36, 38
ou 40 qui concernent des nouvelles collectines exerçant une activite
antibacterienne et antivirale, etc., en particulier, chez l'homme.
L'invention concerne egalement des proteines collectines isolees
contenant une sequence d'acide amine representee par SEQ ID NO:2, 4, 6,
8, 10, 13, 37, 39, ou 41, et des derives et fragments de celles-ci.

English Abstract

Novel scavenger receptors having an SR structure and a collectin-like structure which are proteins having the amino acid sequences of SEQ ID NOS:2, 4 and 24 or proteins having comparable properties thereto, which are usable in clarifying the functions of macrophages and basal immunity, in clarifying the onset mechanisms of various diseases such as arteriosclerosis, diabetic complications, re-constriction after angioplasty and bacterial infection, in diagnosing, preventing and treating these diseases and in developing reagents and drugs therefor; and molecules related thereto such as derivatives or fragments thereof, isolated polynucleotides containing base sequences encoding the same, antibodies and antagonists. A treatment method by using these receptors is also disclosed.

French Abstract

L'invention concerne de nouveaux recepteurs destructeurs possedant une structure SR et une structure du type collectine, ces structures etant des proteines possedant des sequences d'acide amine (SEQ ID NO: 2, 4, et 24) ou des proteines ayant des proprietes comparables. Ces recepteurs destructeurs sont utilises pour epurer les fonctions de macrophages et d'immunité de base, les mecanismes d'apparition de differentes maladies telles que l'arteriosclerose, les complications diabetiques, la recontriction consecutive a une angioplastie, et les infections bacteriennes; pour diagnostiquer, prevenir, et traiter lesdites maladies, et developper des reactifs et des medicaments a partir de ceux-ci. L'invention concerne egalement des molecules associees audits recepteurs telles que des derives ou des fragments de ceux-ci, des sequences de base contenant des polynucleotides isoles codant lesdits recepteurs, des anticorps et des antagonistes. L'invention concerne enfin une technique de traitement utilisant ces recepteurs.

English Abstract

Novel collectin-related molecules expected as exerting antibacterial and antiviral activities, etc. particularly in the human body, namely, a novel collectin gene containing the base sequence represented by SEQ ID NO:1 and a novel collectin containing the amino acid sequence represented by SEQ ID NO:2; and a method with the use of the same.

French Abstract

L'invention concerne de nouvelles molecules liees a la collectine, exerçant une activite antibacterienne et antivirale, en particulier, chez l'homme. L'invention traite plus particulierement d'un nouveau gene de collectine contenant la sequence de base representee par SEQ ID NO:1 et une nouvelle collectine contenant la sequence d'acides amines representee par SEQ ID NO: 2. L'invention a aussi pour objet un procede mettant en oeuvre ces composes.

English Abstract

A production system for homogeneously producing recombinant human mannan-binding proteins (rhMBPs) being comparable in physiological activity to human mannan-binding protein (hMBP), in particular those showing a specific peak at molecular weight of from 1,000 to 1,300 kDa in the absorbance (280 nm) in gel filtration chromatography.

French Abstract

Un systeme de production destine a une production homogene de proteines fixatrices de mannane humaines recombinantes (rhMBP) est comparable, au point de vue activite physiologique, a des proteines fixatrices de mannane humaines (hMBP), en particulier, a celles presentant un pic specifique pour une masse moleculaire comprise entre 1000 et 1300 kDa dans l'absorbance (280 nm) en chromatographie par filtration sur gel.

English Abstract

A recombinant conglutinin which contains a collagen region consisting of six amino acids containing two amino acid sequences Gly-Xaa-Xaa (SEQ ID NO:3, wherein Xaa stands for a protein-constituting amino acid), the neck region of natural conglutinin and the sugar chain recognition region of natural conglutinin, has an antiviral activity (virus neutralizing activity), and is expected to be applicable to drugs; and a process for detecting anti-influenza A virus activity of a mannose-binding protein (MBP) or a human mannose-binding protein (hMBP) involving the step of treating influenza A virus-infected cells with the MBP or hMBP and measuring the level of the suppression of the budding of the virus in the virus-infected cells. An MBP and an hMBP having an anti-influenza A virus activity are disclosed.

French Abstract

Une conglutinine recombinée, laquelle contient une région de collagène constituée de 6 acides aminés contenant deux séquences d'acides aminés Gly-Xaa-Xaa (SEQ-ID-NO:3, dans laquelle Xaa représente un acide amine constituant une protéine), la région de col de la conglutinine naturelle et la région de reconnaissance de chaîne de sucre de conglutinine naturelle, présente une activité antivirale (activité de neutralisation de virus), et on envisage de l'appliquer à des médicaments. L'invention concerne également un procédé de détection d'une activité anti-virus de la grippe A d'une protéine liant le mannose (MBP) ou bien d'une protéine humaine de mannose (hMBP), mettant en œuvre l'étape de traitement de cellules infectées par le virus de la grippe A avec la MBP ou la hMBP, et de mesure du niveau de la suppression du bourgeonnement du virus dans les cellules contaminées par le virus. Une MBP et une hMBP présentant une activité anti-virus de la grippe A sont décrites.
